Abstract
Wells turbine concept depends on utilizing the oscillating air column generated over marine waves to drive a turbine. As a matter of fact, previous researches on the performance analysis of such turbine were based on the first law of thermodynamics only. Nonetheless, the actual useful energy loss cannot be completely justified by the first law because it does not distinguish between the quantity and the quality of energy. Therefore, the present work investigates the second law efficiency and entropy generation characteristics around different blades that are used in Wells turbine under oscillating flow conditions. The work is performed by using time-dependent CFD models of different NACA airfoils under sinusoidal flow boundary conditions. Numerical investigations are carried out for the incompressible viscous flow around the blades to obtain the entropy generation due to viscous dissipation. It is found that the value of second law efficiency of the NACA0015 airfoil blade is higher by approximately 1.5% than the second law efficiency of the NACA0012, NACA0020 and NACA0021 airfoils. Furthermore, it is found that the angle of attack radically affects the second law efficiency and such effect is quantified for NACA0015 for angle of attack ranging from −15° to 25°.

1. Introduction
The major challenge facing oscillating water column systems is to find efficient and economical means of converting oscillating flow energy to unidirectional rotary motion, for driving electrical generators. A novel resolution for such challenge is the Wells turbine [1–4], see Fig. 1(a, b) due to its simple and efficient operation. The Wells turbine has already been applied in practice to gain energy from marine waves. In the past two decades, experimental research of Wells turbine has mainly focused on improving the turbine performance with emphasis on the overall operational characteristics. The airfoils sections that are used in Wells turbine have been extensively investigated in aeronautical applications. However, the operating conditions in Wells turbine are completely different from such of the aeronautical applications. In Wells turbine, the rotor contains multiple blades, which are confined by a shroud aiming at harnessing the flow momentum to drive the rotor with the maximum torque. The flow physics in such situations are still having several issues to investigate; besides, the dynamical complexity resulting from an oscillating water column driven by random irregular marine waves.

Second law analysis of energy conversion systems has become an important tool for optimization and development during the past decade. In fact, the second law of thermodynamics is more reliable than the first law of thermodynamics analysis due to the limitation of the first law efficiency in a heat transfer engineering systems as well as heat transfer, mass transfer, viscous dissipation, etc. Moreover, the second law can be used as the sources of entropy generation [5,6]. Consequently, This work utilizes time-dependent numerical models of different NACA four-digit series blade profile under oscillating flow conditions. Numerical investigations are carried out for the flow around Wells turbine blades using sinusoidal wave boundary conditions to perform as realistic
characterization as possible of the flow field upstream and downstream of the turbine during the passage of the wave. The Gouy–Stodola theorem [7] has been used to compute the second law efficiency from the results of the numerical simulations. This theorem postulates the difference between reversible and actual works in any thermodynamic system which is the entropy generation in such system, as discussed later in section 4. Such theorem is the foundation for the entropy generation minimization method proposed by Bejan [8] to optimize finite size thermodynamic systems.

A thorough literature survey has revealed that the second law analysis of the oscillating flow around Wells turbine has not been conducted before. However, this section briefly reviews the most relevant studies to accentuate the scope of the present work. In a number of previous studies, it is concluded that the delay of stall onset contributes in improving Wells turbine performance. This delay can be achieved by setting guide vanes on the hub near the rotor [9].

As far as the running and starting characteristics of the Wells turbine are concerned, Wells turbine with 3D guide vanes are superior to those with 2D guide vanes or without guide vanes [10,11]. Furthermore, the presence of end plates is investigated experimentally and numerically by Refs. [12,13] where they conclude that the Wells turbine with end plates is superior to those of the original Wells turbine (which was investigated also in this work) because the peak efficiency and the stall margin increases by approximately 4% and its characteristics are dependent on the size and position of end plate.

Three dimensional numerical simulations are performed by Thakker et al. [14] in order to analyze the performance of a Wells turbine with CA9 blade profile, a maximum efficiency of 70% is obtained. Moreover, Kim et al. [15] uses numerical simulation to study the effect of the blade sweep on the performance of a Wells turbine using either NACA0020 or CA9 blade profiles. They were found that the performance of the Wells turbines with NACA0020 and the CA9 blades are influenced by the blade sweep. As the optimum rotor shape for a NACA0020 blade, a blade sweep ratio 35% is identified to deliver the optimum performance. In general, the overall turbine performance for the NACA0020 is better than such of the CA9, Also, Takao et al. [16], presents experimentally the suitable choice the sweep ratio of 0.35 for the cases of CA9 and HSIM 15-262123-1576. In another study [17], the characteristics of a Wells turbine with NACA0021 constant chord blades are investigated. They find from the numerical results that the wakes behind the turbine blades merge rigorously in the portion of radius ratio from 0.45 to 1.0, which leads the turbine to stall.

One and two stage Wells turbines involving symmetric airfoils and Non-Symmetric airfoils are investigated by Mohamed [18,19]. Numerical optimization procedure has been carried out to optimize the performance of the turbine as a function of the non-dimensional gap between the two rotors. It is leading to an optimal value of the non-dimensional gap (The distance between the two stages/the blade chord) near 0.85 when considering the operating range. Moreover, the Evolutionary Algorithms are used to estimate the optimum shape with an increase of efficiency (by 2.1%) and of tangential force coefficient (by 6%), compared to the standard NACA 2421, as well as the one-stage the optimum shape with an increase of efficiency (by 1%) and of tangential force coefficient.
and turbulent flow is modeled using the Realizable k-ε model, Transport equation of turbulent kinetic energy (k)

\[
\frac{\partial}{\partial t} (\rho k) + \frac{\partial}{\partial x_i} (\rho u_i k) = \frac{\partial}{\partial x_j} \left[ \left( \frac{\mu + \mu_t}{\sigma_k} \right) \frac{\partial k}{\partial x_j} \right] + \frac{\mu_t}{\varepsilon} S_k^2 - \rho e
\]  

(3)

Specific dissipation rate equation is:

\[
\frac{\partial}{\partial t} (\rho e) + \frac{\partial}{\partial x_i} (\rho u_i e) = \frac{\partial}{\partial x_j} \left[ \left( \frac{\mu + \mu_t}{\sigma_{\varepsilon}} \right) \frac{\partial e}{\partial x_j} \right] + C_1 \mu S_{ri} - C_2 \rho \frac{e^2}{k + \varepsilon}
\]  

(4)

Where \(C_1 = \max \left( 0.43, \frac{a}{\pi^2} \right) \), \(C_2 = 1.9\)

\[C_\mu = \frac{1}{A_0 + A_1 U'^2} \]

(5)

Where

\(A_0 = 4.0\), \(U^r = \sqrt{S_{ij} S_{ij} + \Omega_{ij} \Omega_{ij}}, A_3 = \sqrt{6} \cos \left( \frac{1}{2} \arccos \left( \sqrt{6} W \right) \right), W = \frac{\sqrt{S_{ij} S_{ij}}}{v} \) and the vorticity tensor \(\Omega_{ij} = \frac{1}{2} \left( \frac{\partial u_i}{\partial x_j} - \frac{\partial u_j}{\partial x_i} \right)\) where \(\Pi\) is the Reynolds averaged velocity vector. The present study adopts one and two-equation turbulence models to close the Reynolds stress term \((-\rho \overline{u' \overline{v'}}\)) of the RANS equation [42] as shown in the following section. The transport equations of such models can be found in turbulence modeling texts such as [43]. The second law of thermodynamic defines the net-work transfer rate \(W\) as [8]:

\[W = W_{rev} - T_0 S_{gen} \]

(6)

It is possible to express the irreversible entropy generation in terms of the derivatives of local flow quantities in the absence of phase changes and chemical reactions. The two dissipative mechanisms in viscous flow are the strain-originated dissipation and the thermal dissipation Which correspond to a viscous and a thermal entropy generation respectively [39]. Thus, it can be written,

\[S_{gen} = S_V + S_{th} \]

(7)

In incompressible isothermal flow, such as the case in hand, the thermal dissipation term vanishes. The local viscous irreversibilities therefore can be expressed as:

2. Mathematical model and numerical approach

The mathematical model consists of the governing equations of turbulent incompressible unsteady flow in two-dimensional generalized coordinates, which can be written in vector notations as [41]:

Continuity:

\[
\frac{\partial}{\partial t} + \frac{\partial}{\partial x_i} (\rho \overline{u_i}) = 0
\]  

(1)

RANS:

\[
\rho \frac{\partial \overline{u_i}}{\partial t} + \frac{\partial}{\partial x_j} (\rho \overline{u_i} \overline{u_j}) = -\frac{\partial p}{\partial x_j} + \frac{\partial}{\partial x_j} \left[ \mu \left( \frac{\partial \overline{u_i}}{\partial x_j} + \frac{\partial \overline{u_j}}{\partial x_i} - \frac{2}{3} \frac{\partial \overline{u_l}}{\partial x_l} \right) \right] + \frac{\partial}{\partial x_j} \left( -\rho \overline{u_i} \overline{u'} \right)
\]  

(2)

Fig. 2. The computational domain showing the grid, boundary conditions and dimensions as a function of chord length (L).
\[ \phi = \frac{\mu}{T_o} \]

where \( \phi \) is the viscous dissipation term, that is expressed in two dimensional Cartesian coordinates as \([39]\):

\[ \phi = 2 \left[ \left( \frac{\partial u}{\partial x} \right)^2 + \left( \frac{\partial v}{\partial y} \right)^2 \right] + \left( \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right)^2 \]  

(9)

and the global entropy generation rate is hence expressed as:

\[ S_G = \iint_S \phi \, dy \, dx \]  

(10)

and finely the second law efficiency is defined as:

\[ \eta_S = \frac{KE}{KE + S_G} \]  

(11)

where

\[ KE = \frac{1}{2} V^2 \]  

(12)

but the efficiency in first law of thermodynamics \((\eta_f)\) is defined as:

\[ \eta_f = \frac{\text{Net Output}}{\text{Total work Input}} \]  

(13)

2.1. Numerical model details

The computational domain is discretized to Cartesian structured finite volume cells using GAMBIT code. Dirichlet boundary conditions are applied on the domain for the solution of momentum and continuity equations. The application of such boundary condition types \([21, 44–46] \) matches the Green–Gauss cell based evaluation.

Numerous tests accounting for different interpolation schemes used to compute cell face values of the flow field variables, the variables of governing equation which are velocity and pressure, as well as convergence tests have been undertaken. The second order upwind interpolation scheme is used in this work because it yields results which are approximately similar to such yielded by third order MUSCL scheme in the present situation. It is also found that the solution reaches convergence when the scaled residuals approaches $10^{-5}$. At such limit, the flow field variables hold constant values with the application of consecutive iterations. Fig. 2; show the dimensions of whole computational domain and location of airfoil. Fig. 3; show the grid distribution near the wall of the airfoil.

The axial flow of Wells Turbine is modeled as a sinusoidal wave in this simulation. Therefore, Inlet boundary conditions are set to change as time. In order to apply the inlet boundary condition, inlet velocity with periodic function (see Fig. 4) is generated as follows.

$$V = V_0 + V_a \sin(2 \pi ft)$$ \hspace{1cm} (14)

where $t$ is time period 6.7 s are set as one period in this simulation considering to the literature survey [22,23,33]. Time step is set as 0.00009 s in order to satisfy CFL (Courant Friedrichs Lewy) [47] condition equal to 1. The sinusoidal wave condition create various Reynolds number up to $2.4 \times 10^5$ and this maximum value which is taken from many references such as [13,18,20–23,25,48,49].

Regarding the angle of attack, it covers wide range of angles of attack in both directions (positive and negative) but it doesn’t need more than this value because the stall condition [50].

### 2.2. Numerical model validation

In order to ensure that the numerical model is free from numerical errors, several grids are tested to estimate the number of grid cells required to establish a grid-independent test. Table 1 shows the specifications of different grids used in such test. Fig. 5; shows the pressure coefficient ($C_p$) distribution on the upper and lower surfaces of the airfoil as computed by the four grids. Grid C and D have the same result, but the latter one required less time. So, Grid C is chosen to conduct the analysis presented hereafter.

Many turbulence models are used to model the oscillating flow around the object in order to determine the model which gives the best agreement with experimental data adopted from Ref. [51]. The best result for S-A, $k-\omega$ SST and the Realizable $k-\varepsilon$ model but the latter one required less time [52]. As for the near-wall treatment in both $k$-epsilon and S-A models have used the log law of the wall but for $k$-omega models have used $y$ plus less than one. This experimental data for unsteady forces acting on a square cylinder in oscillating flow with nonzero mean velocity are measured [51] where the oscillating air flows are generated by a unique AC...
servomotor wind tunnel. The generated velocity histories are almost exact sinusoidal waves. The measured unsteady $F_D$ is computed from the Morison equation for the in-line force acting on the cylinder per unit length:

$$F_D = \frac{1}{2} \rho B C_D |U| |U| + \rho A \tilde{C}_D \dot{U}$$

(15)

where $\dot{U} = dU/dt$ and the non-dimensional coefficient $\tilde{C}_D$ is the inertia coefficient of the unsteady in-line force. This non-dimensional coefficient is evaluated depend on \[53,54\].

This data is the most experimental data that have available information for the sinusoidal flow condition to validate our work; therefore, it is adopted in the following simulation cases.

3. Results and discussion

3.1. Evaluation of the second law efficiency of different NACA airfoils

The numerical simulations are used to obtain local entropy viscosity predictions of the different airfoil sections. Fig. 7(a) and (b) highlight the entropy behavior when a flow is accelerating in compression and suction cycle. Consequently, the entropy generation ratio varies with the Reynolds number at certain angle of attack equal to $2\degree$. The change of Reynolds number values is due to using sinusoidal wave boundary conditions. At low values of Reynolds number the stall condition occur at small value of angle of attack \[50\]. Hence, $2\degree$ angle of attack is chosen to avoid the stall condition.

The Reynolds number is calculated from equation (14). Otherwise, the value of Reynolds number in this study can be controlled by the value of velocity while keeping the other parameters.
constant.

$$\text{Re} = \frac{VLp}{\mu}$$  \hspace{1cm} (16)

The Reynolds number has radical effect on the entropy generation. This is obvious in the accelerating flow in compression and suction cycle in Fig. 7 (a, b), where Reynolds number increase from $6 \times 10^4$ to $1.2 \times 10^5$. As a result, the global entropy generation rate (i.e. integral) has increased correspondingly for more than two folds of all airfoils. However, when Reynolds number has increased further to $1.7 \times 10^5$ ($2 \times 10^5$ for NACA0012 at compression cycle) the global entropy generation rate exhibited unintuitive values ranging from 50% less to 40% lower than the corresponding value at Reynolds number equal to $1.2 \times 10^5$ for all airfoils. The reason behind such phenomena can be attributed to the nonlinear complexity of the viscous dissipation term (equation (9)) where both the square of mean rate of strain and velocity divergence contributes to the local viscous irreversibilities. This phenomenon suggests that possible existence of critical Reynolds number at which viscous irreversibility takes minimum values. At high Reynolds number (greater than $2 \times 10^5$) the change in velocity value, see equation (14), is smaller than low Reynolds number. Where, at 120000 Reynolds number the velocity equal to 17.5 m/s, then it increases to 24.8 m/s at 170000 Reynolds number (41% increase rate). After that, it reaches to 200000 Reynolds number with velocity equal to 30.3 m/s (22% increase rate). On the other hand, at high Reynolds number (230000) the velocity reach to maximum value equal to 35.04 m/s (3% increase rate). Then, at 240000 Reynolds number the velocity reach to maximum value equal to 35.04 m/s (3% increase rate), see Fig. 4. This leads to smaller change in flow field and entropy generation. The last one was dependent on velocity analysis.

Fig. 12. Comparisons between second law efficiency during the sinusoidal wave cycle for four different airfoils.

Fig. 13. Contours of Exergy around the blade of NACA0015 for angle of attack $2^\circ$ at different time and different velocity along the sinusoidal wave, a) at $t = 0.837 \text{ s}$ and $V = 24.778 \text{ m/s}$, b) $t = 1.674 \text{ s}$ and $V = 35.04 \text{ m/s}$, c) $t = 2.511 \text{ s}$ and $V = 24.824 \text{ m/s}$, d) $t = 3.348 \text{ s}$ and $V = 0.10565 \text{ m/s}$, e) $t = 4.185 \text{ s}$ and $V = -24.7 \text{ m/s}$, f) $t = 5.022 \text{ s}$ and $V = -35 \text{ m/s}$, g) $t = 5.859 \text{ s}$ and $V = -24.79 \text{ m/s}$, h) $t = 6.696 \text{ s}$ and $V = -0.0913 \text{ m/s}$.
However, in Fig. 8 (a, b) for decelerating flow in compression and suction cycle when Reynolds number, in Fig. 8 (a), is decreased further to $1.2 \times 10^5$ the global entropy generation rate exhibited unintuitive values ranging from 94% (NACA0021, NACA0020) less to 59% (NACA0015) and 15% for (NACA0012) higher than the corresponding value at Reynolds number equal to $1.7 \times 10^5$. For decelerating flow in suction cycle the global entropy generation rate, at Reynolds number equal to $1.2 \times 10^5$, exhibited unintuitive values ranging from 135% (NACA0012) less to 83% (NACA0020) and 68% (NACA0021, NACA0015) which is higher than the corresponding value at Reynolds number equal to $1.7 \times 10^5$. Then, when Reynolds number is decreased further to a minimum value the global entropy generation rate is decreased also to minimum value and not equal to zero. From Figs. 7 and 8, at maximum Reynolds number, the NACA0012 give lower entropy generation rate than other airfoil. From Fig. 9, it is concluded that the NACA0015 give lower maximum value for the global entropy generation rate than other airfoil in both cycles. The NACA0015 airfoil section gives less average value ranging from 20% less to 10% of the global entropy generation rate during the sinusoidal wave cycle see Fig. 10.

</table>
confirm these results we have made a comparison between the second law efficiency for four different airfoils at compression and suction cycle (Fig. 11) and also for the total average efficiency during the sinusoidal wave cycle (Fig. 12), NACA0015 gives best efficiency when it is compared with other airfoils in both compression and suction cycle and therefore in total sinusoidal wave cycle ranging from 2% less to 1%. In four different airfoils and at certain angle of attack, the efficiency for compression cycle higher than suction cycle ranging from 1% less to 0.3%.

Equation (17) is defining the exergy value, which can be written as:

\[
\text{Exergy} = KE + S_G
\]  

(17)

Contours of Exergy around the blade of NACA0015 for angle of attack 2° at different time and different velocity along the sinusoidal wave can be seen in Fig. 13 that the positive value of velocity refers to compression cycle and the negative value refers to suction cycle. From this figure it can be observed that as the velocity increase the value of exergy around the blade increase, otherwise, the leading and trailing edge always have the lowest value, but at compression cycle the area around the trailing edge has lower value than the leading edge, and in the suction cycle the area around the leading edge has lower value than trailing one.

3.2. Effect of the angle of attack on entropy generation

The increase of angle of attack has a direct effect to the entropy generation in the flow over the airfoil which is similar to the effect of Reynolds number. However, as shown in Fig. 14(a) and (b), NACA0015 airfoil has a different entropy generation signature for different angles of attack listed in Table 2. For accelerating flow in compression cycle, Fig. 14(a) at Reynolds number equal to 1.2 × 10^5 the maximum value of global entropy generation rate occurs due to 2° angle of attack but the minimum value of it occurs due to −15° angle of attack. The 17° angle of attack gives maximum global entropy generation rate at 1.7 × 10^5 Reynolds number, and the minimum value occurs due to −11° at the same Reynolds number. Finally, at Reynolds number equal to 2.3 × 10^5 and 2.4 × 10^5 the maximum global entropy generation rate occurs due to 17° and the minimum value occurs due to 5°.

The trend of global entropy generation rate at suction cycle is different from the compression cycle at various angles which can be seen in Fig. 14(b). For decelerating flow in suction cycle at Reynolds number equal to 1.7 × 10^5, the maximum global entropy generation rate occurs at 5° angle of attack and the minimum value occurs due to 25°. For Reynolds number equal to 1.2 × 10^5 the maximum global entropy generation rate occurs due to 2° angle of attack and the minimum value due to 25°. Low angles of attack around zero, both positive and negative direction have higher global entropy generation rate and lower entropy efficiency except at 17° so we can note that there is unexpected increase in the value of global entropy generation rate accompanied by a lack of the second law efficiency, see Figs. 15 and 16. As for angle of attack from −5 to 5° the entropy efficiency for compression cycle higher than the suction cycle, but when the angle of attack increase in both directions the efficiency for suction cycle exceeds the compression cycle, see Fig. 17. At same angle of attack but in different direction, the positive direction gives higher efficiency than the negative one. For example, the second law efficiency for 5° higher approximately 0.5% than −5° and approximately 0.1% between 11° and −11° and finally 0.3% between 15° and −15°.

4. Conclusions

Second law analysis of Wells turbine requires accurate estimation of flow irreversibilities around the turbine blades. Two-dimensional incompressible unsteady flow simulations of different airfoils reveals that the geometry and the operating conditions have radical effects on the global entropy generation rate in the flow around turbine airfoil. The main conclusions are summarized as follows.

Fig. 15. The global entropy generation rate during the sinusoidal wave cycle for different angle of attack. The dotted line indicates a fitting with a Gaussian distribution function.

Fig. 16. Second low efficiency during the sinusoidal wave cycle for different angle of attack.

Fig. 17. Comparisons between second law efficiency during the compression and suction wave cycle for different angle of attack.
1 The relationship between the Reynolds number and the global entropy generation rate haven’t a direct correlation but when compare between four airfoils at certain angle of attack the maximum global entropy generation rate occurs at Reynolds number of $1.2 \times 10^5$ and at $1.7 \times 10^5$ ($2 \times 10^5$ for NACA0012 in compression cycle) less than halved.

2 NACA0015 gives less global entropy generation rate and higher efficiency compare with other airfoil.

3 The efficiency for four different airfoils in compression cycle is higher than suction cycle at $2^\circ$ angle of attack. But when the angle of attack increase, the efficiency for suction cycle increase also more than the compression one.

4 At zero and low angle of attack we have higher global entropy generation rate than at high angle of attack.

5 From the study of the behavior of four different airfoils, NACA0015 isn’t the best airfoil in all condition. For examples, at maximum Reynolds number NACA0012 gives less global entropy generation rate and NACA0020 create the minimum value, so it is a good concept to create an optimum design airfoil gives better result than NACA0015.

6 In general the global entropy generation rate due to viscous dissipation is a very sensitive indicator for airfoils behavior at any change in design parameters, the operating condition and also being affected by flow direction.
